# HETE Gamma-ray Bursts: 6 Major Scientific Insights in Past 1.5 Years

## GRB020531:

First detection of short GRB with prompt optical/X-ray followup

## GRB020813:

X-ray lines from  $\alpha$  particle nuclei (Chandra spectra)

## GRB020903:

Elucidation of "X-ray Flashes"

## GRB021004:

Refreshed shock or inhomogeneous jet (NASA SSU)

## GRB021211:

Insight into "Optically Dark" GRB Mystery

## GRB030329:

GRB-SN Connection (SN2003dh;  $z=0.17$ )

Courtesy G. R. Ricker

# “X-Ray Flashes”

- Defining “X-ray flashes” (Heise et al. 2000) as bursts for which  $\log(S_x/S_{\text{gamma}}) > 0$  (i.e., > 30 times that for “normal” GRBs)
  - ~ 1/3 of bursts localized by HETE-2 are XRFs
  - ~ 1/3 are “X-ray-rich” GRBs
- Nature of XRFs is largely unknown
- XRFs may provide unique insights into
  - Structure of GRB jets
  - GRB rate
  - Nature of Type Ic supernovae

# HETE-2 X-Ray Flashes vs. GRBs

Sakamoto et al. (2004)

## XRF 020903: Discovery of Optical Afterglow

---

Soderberg et al. (2002)

Palomar 48-inch Schmidt images: 2002 Sep 6  
(left image), 2002 Sep 28 (middle image),  
subtracted image (right image)

# XRF 020903: Implications

---

- ❑ HETE-2 and optical follow-up observations of GRB020903 show that this XRF:
  - ❑ Lies on the extensions of the above distributions
  - ❑ Lies on an extension of the Amati et al. (2002) relation
  - ❑ Host galaxy is copiously producing stars, similar to those of GRBs
  - ❑ Host galaxy has a redshift  $z = 0.25$ , similar to those of GRBs
- ❑ These results provide evidence that GRBs, X-ray-rich GRBs, and X-Ray Flashes are closely related phenomena

# HETE-2 Observations of XRF 030723

Butler et al. (2004)

# XRF 030723: Optical Afterglow

Fynbo et al. (2004)

Tominaga et al. (2004)

- Increase at  $\sim 15$  days after burst might be due to SN component – or possibly, jet structure

## Density of HETE-2 Bursts in ( $S$ , $E_{\text{peak}}$ )-Plane

“Global Properties of XRFs and X-Ray-Rich GRBs Observed by HETE-2,”  
Sakamoto et al. (2004; astro-ph/0409128)

## Dependence of GRB Peak Spectral Energy ( $E_{\text{peak}}$ ) on Burst Isotropic Radiated Energy ( $E_{\text{iso}}$ )

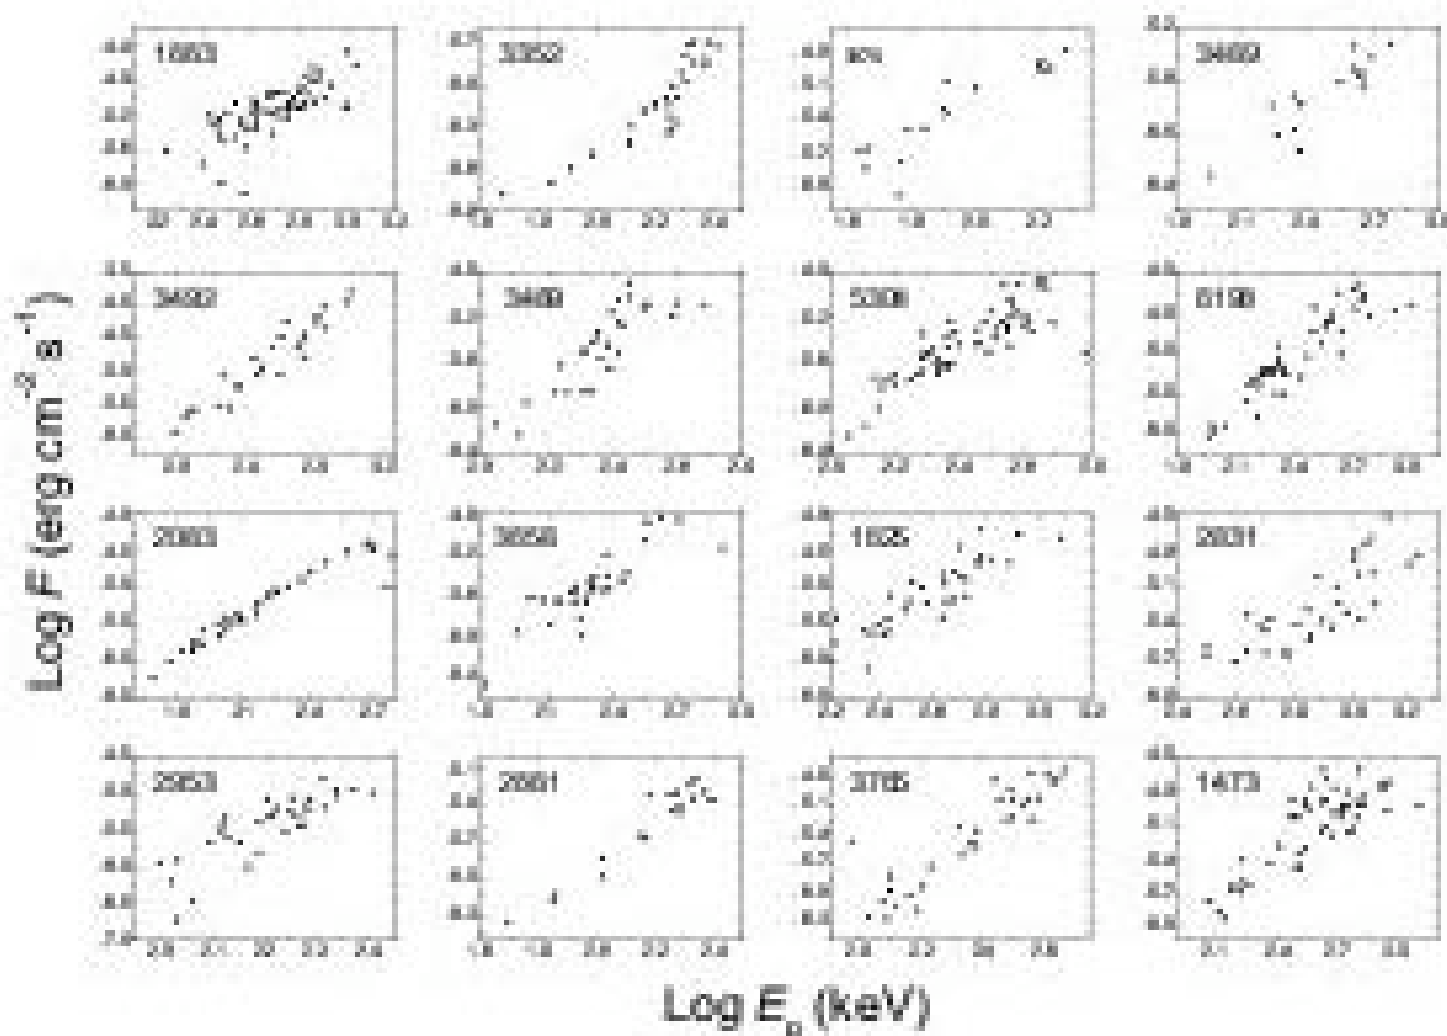

HETE-2 results confirm & extend the Amati et al. (2002) relation:

$$E_{\text{peak}} \sim \{E_{\text{iso}}\}^{0.5}$$

# $E_{\text{iso}} - E_{\text{peak}}$ Relation *Within* BATSE GRBs

Liang & Dai (2004)

## Implications of HETE-2 Observations of XRFs and X-Ray-Rich GRBs

---

- ❑ HETE-2 results, when combined with earlier results:
  - ❑ Provide strong evidence that properties of XRFs, X-ray-rich GRBs, and GRBs form a continuum
  - ❑ Key result: *approximately equal numbers of bursts per logarithmic interval* in all observed properties
  - ❑ Suggest that these three kinds of bursts are closely related phenomena

# Observations of XRFs Are Stimulating New Theoretical Ideas

---

## □ XRF & GRB Jet Structure and Burst Rates

- Quasi-Universal Gaussian Jets: A Unified Picture for GRBs & XRFs (B. Zhang, X. Dai, N. M. Lloyd-Ronning & P. Meszaros), *ApJ*, 601, L119 (2004)
- XRF 030723: Evidence for a Two-Component Jet (Y. F. Huang, X. F. Wu, Z. G. Dai, H. T. Ma & T. Lu), *ApJ*, 605, 300 (2004)
- XRF 020903: Sub-Luminous & Evidence for A Two-Component Jet (A. Soderberg et al.), *ApJ*, 606, 994 (2004)
- A Unified Jet Model of XRFs, X-Ray-Rich GRBs, & GRBs (D. Q. Lamb, T. Q Donaghy & C. Graziani, *ApJ*, in press (astro-ph/0312634) (2004)
- Unified Model of XRFs, X-Ray-Rich GRBs & GRBs (R. Yamazaki, K. Ioka & T. Nakamura), *ApJ*, 607, 103 (2004)
- Gaussian Universal Jet Model of XRFs & GRBs (X. Dai & B. Zhang), *ApJ*, submitted (2004)

## □ XRF—SN Connection

- Possible SN in Afterglow of XRF 030723 (J. P. U. Fynbo et al.) *ApJ*, 609, 962 (2004)
- Model of Possible SN in Afterglow of XRF 030723 (Tominaga, N., et al.), *ApJ*, 612, 105 (2004)
- XRFs & GRBs as a Laboratory for the Study of Type Ic SNe ((D. Q. Lamb, T. Q Donaghy & C. Graziani), *New Astronomy Reviews*, in press (2004)
- GRB-SN Connection: GRB 030329 & XRF 030723 (J. P. U. Fynbo et al.), *Santa Fe GRB Workshop Proceedings*, in press (2004)

## □ Relativistic Beaming and Off-Axis Viewing Models of XRFs

- Peak Energy-Isotropic Energy Relation in the Off-Axis GRB Model (R. Yamazaki, K. Ioka & T. Nakamura), *ApJ*, 606, L33 (2004)
- Off-Axis Viewing as the Origin of XRFs (S. Ddo, A. Dr & A. De Rujula), *A&A*, in press (astro-ph/0308297) (2004)
- XRFs from Off-Axis Non-Uniform Jets (Z. P. Jin & D. M. Wei), *A&A*, submitted (astro-ph/0308061) (2004)

## X-Ray and Optical Afterglows of XRFs Are *Also* Faint

Lamb, Donaghy & Graziani (2004)

- ❑ X-ray and optical afterglows of XRFs are *much fainter* than those of GRBs
- ❑ Left panel: slope =  $0.74 \pm 0.17$ ; right panel: slope =  $-0.70 \pm 0.15$  (68% CL)  
=> tantalizing evidence that efficiency of prompt emission is *much less* for XRFs than for GRBs (as expected from  $V \Leftrightarrow L$  estimator)

# X-Ray Flashes vs. GRBs: HETE-2 and *Swift* (BAT)

Even with the BAT's huge effective area ( $\sim 2600 \text{ cm}^2$ ), only HETE-2 can determine the spectral properties of the most extreme half of XRFs.

# Ability of HETE-2 and *Swift* to Measure $E_{\text{peak}}$ and $S_{\text{bol}}$ of XRFs

## $E_{\text{peak}}^{\text{(estimated)}}$ vs. $E_{\text{peak}}$ :

Shaded areas are 68% confidence regions

**Swift (red):**

well-determined for  $E_{\text{peak}} > 20$  keV

undetermined for  $E_{\text{peak}} < 20$  keV

**HETE-2 (blue):**

well-determined down to  $E_{\text{peak}} \sim 3$  keV

## $S_{\text{bol}}^{\text{(estimated)}}$ vs. $S_{\text{bol}}$ :

Shaded areas are 68% confidence regions

**Swift (red):**

well-determined for  $E_{\text{peak}} > 20$  keV

undetermined for  $E_{\text{peak}} < 20$  keV

**HETE-2 (blue):**

well-determined down to  $E_{\text{peak}} \sim 3$  keV

# Conclusions

---

- ❑ HETE-2 has provided strong evidence that XRFs, “X-ray-rich” GRBs, and GRBs are closely related phenomena
- ❑ XRFs provide unique insights into
  - ❑ structure of GRB jets
  - ❑ GRB rate
  - ❑ nature of Type Ic SNe
- ❑ Confirmation will require *prompt*
  - ❑ localization of many XRFs
  - ❑ determination of  $E_{\text{peak}}$
  - ❑ identification of X-ray and optical afterglows
  - ❑ determination of redshifts
- ❑ HETE-2 is ideally suited to do *the first two*, whereas *Swift* (with  $E_{\text{min}} \sim 15$  keV) is not; *Swift* is ideally suited to do *the second two* whereas HETE-2 cannot
- ❑ **Prompt *Swift* XRT and UVOT observations of HETE-2 XRFs can therefore greatly advance our understanding of XRFs**

# HETE is Solving Mystery of “Optically Dark” GRBs

- ❑ 13 of 15 HETE-2 SXC plus WXM localizations have led to ID of an optical/IR afterglow
- ❑ These bursts are a “fair sample” of all bursts localized by HETE-2 above SXC threshold
- ❑ WXM localizations are the key to XRF science

# $E_{\text{gamma}}$ — $E_{\text{peak}}$ Relation

Ghirlanda et al. (2004)

# GRBs Have “Standard” Energies

Frail et al. (2001); Kumar and Panaitescu (2001)

Bloom et al.(2003)

# Power-Law Universal Jet Model

---

- $E_{\text{iso}}(\theta_{\text{view}}) \sim E_{\text{gamma}}(\theta_{\text{view}})^{-2}$
- Exponent = -2 is necessary to recover the Frail et al. (2001) result (see, e.g., Rossi et al. 2002, Zhang & Meszaros 2002)
- Most viewing angles lie at  $\sim \theta_{\text{max}}$  or  $\sim 90^\circ$  to jet axis (whichever is larger) because that is where most of solid angle is
- This implies that most bursts (and most bursts that we see) have large  $\theta_{\text{view}}$ 's, and therefore small  $E_{\text{iso}}$ 's,  $L_{\text{gamma}}$ 's,  $E_{\text{peak}}$ 's, etc. (Rossi et al. 2002, Zhang & Meszaros 2002, Perna et al. 2003)

# Uniform Jet Model

- ❑ Frail et al. (2000) result  $\Rightarrow E_{\text{iso}} \sim E_{\text{gamma}}/\Omega_{\text{jet}}$
- ❑ Amati et al. (2002) relation  $\Rightarrow$   
$$E_{\text{peak}} \sim (E_{\text{iso}})^{1/2} \sim (E_{\text{gamma}}/\Omega_{\text{jet}})^{1/2}$$
- ❑ HETE-2 results show that  $E_{\text{iso}}$  spans  $\sim 5$  decades!
- ❑ HETE-2 results imply  $N(\Omega_{\text{jet}}) \sim \Omega_{\text{jet}}^{-2} \Rightarrow$ 
  - ❑ there are many more bursts w. *small*  $\Omega_{\text{jet}}$ 's than large; however, we don't see most of them
  - ❑ we see  $\sim$  equal numbers of bursts per logarithmic decade in *all* properties ( $\Omega_{\text{jet}}$ ,  $E_{\text{iso}}$ ,  $E_{\text{peak}}$ ,  $L_{\text{gamma}}$ ,  $L_{\text{x}}$ ,  $L_{\text{R}}$ , etc.)!

# Simulations of Observed GRBs

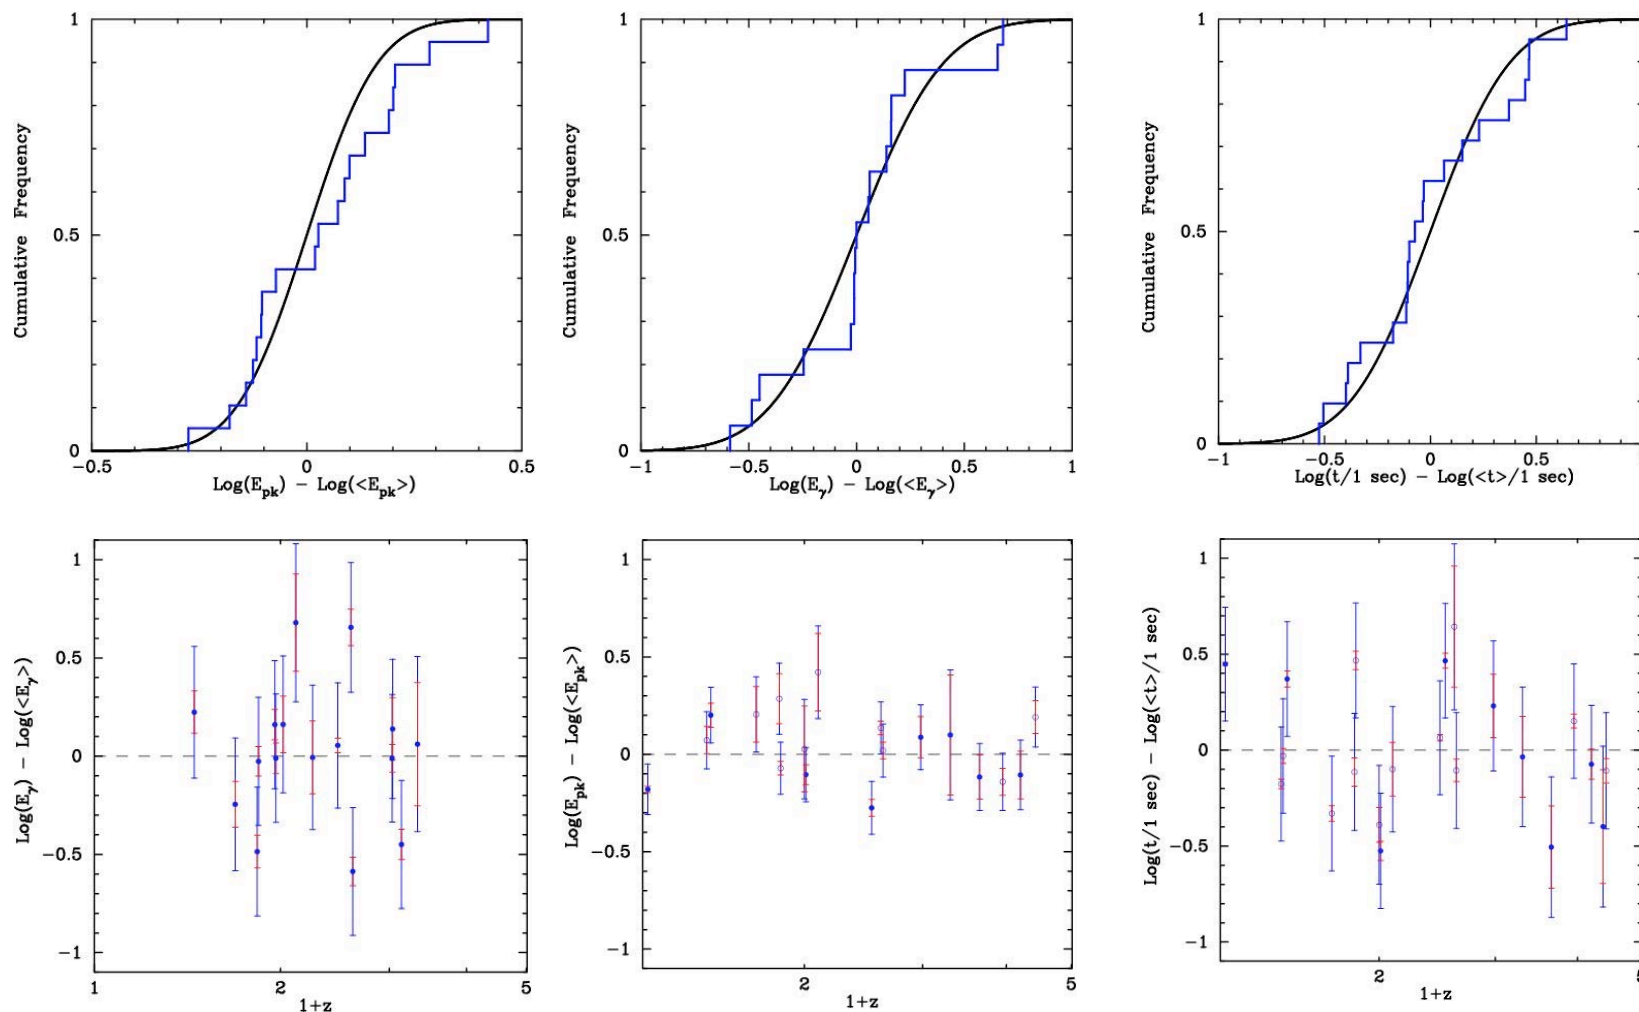

---

- ❑ Our approach is the following:
  - ❑ We first model the bursts in the source frame
  - ❑ We then propagate the bursts from the source frame to the Earth, using the cosmology that we have adopted
  - ❑ We determine which bursts are observed, using the properties of the instruments that observe them
- ❑ We execute our simulations as follows:
  - ❑ For each burst, we obtain a redshift  $z$  and a jet opening solid angle  $\Omega_{\text{jet}}$  by drawing from specific distributions
  - ❑ We introduce three Gaussian smearing functions to generate
    - ❑ Spread in jet energy ( $E_{\text{gamma}}$ )
    - ❑ Spread in  $E_{\text{peak}}$  around the Amati et al. (2002) relation
    - ❑ Spread in the timescale  $T$  that converts fluence to flux
  - ❑ Using these five quantities, we calculate various rest-frame quantities ( $E_{\text{iso}}$ ,  $E_{\text{peak}}$ , etc.)
  - ❑ Finally, we construct a Band function for each burst and transform it to the observer frame, which allows us to
    - ❑ Calculate fluences and peak fluxes
    - ❑ Determine if the burst would be detected by various instruments

# Gaussian Smearing Functions

- ❑ Observed distributions are well-fit by narrow Gaussians
- ❑ No evidence for evolution of any of Gaussians w. redshift  $z$

# $E_{\text{iso}} - E_{\text{peak}}$ Relation

Lloyd-Ronning, Petrosian & Mallozzi (2000); Amati et al. (2002);  
Lamb et al. (2003)

## Comparison of Universal and Uniform Jet Models

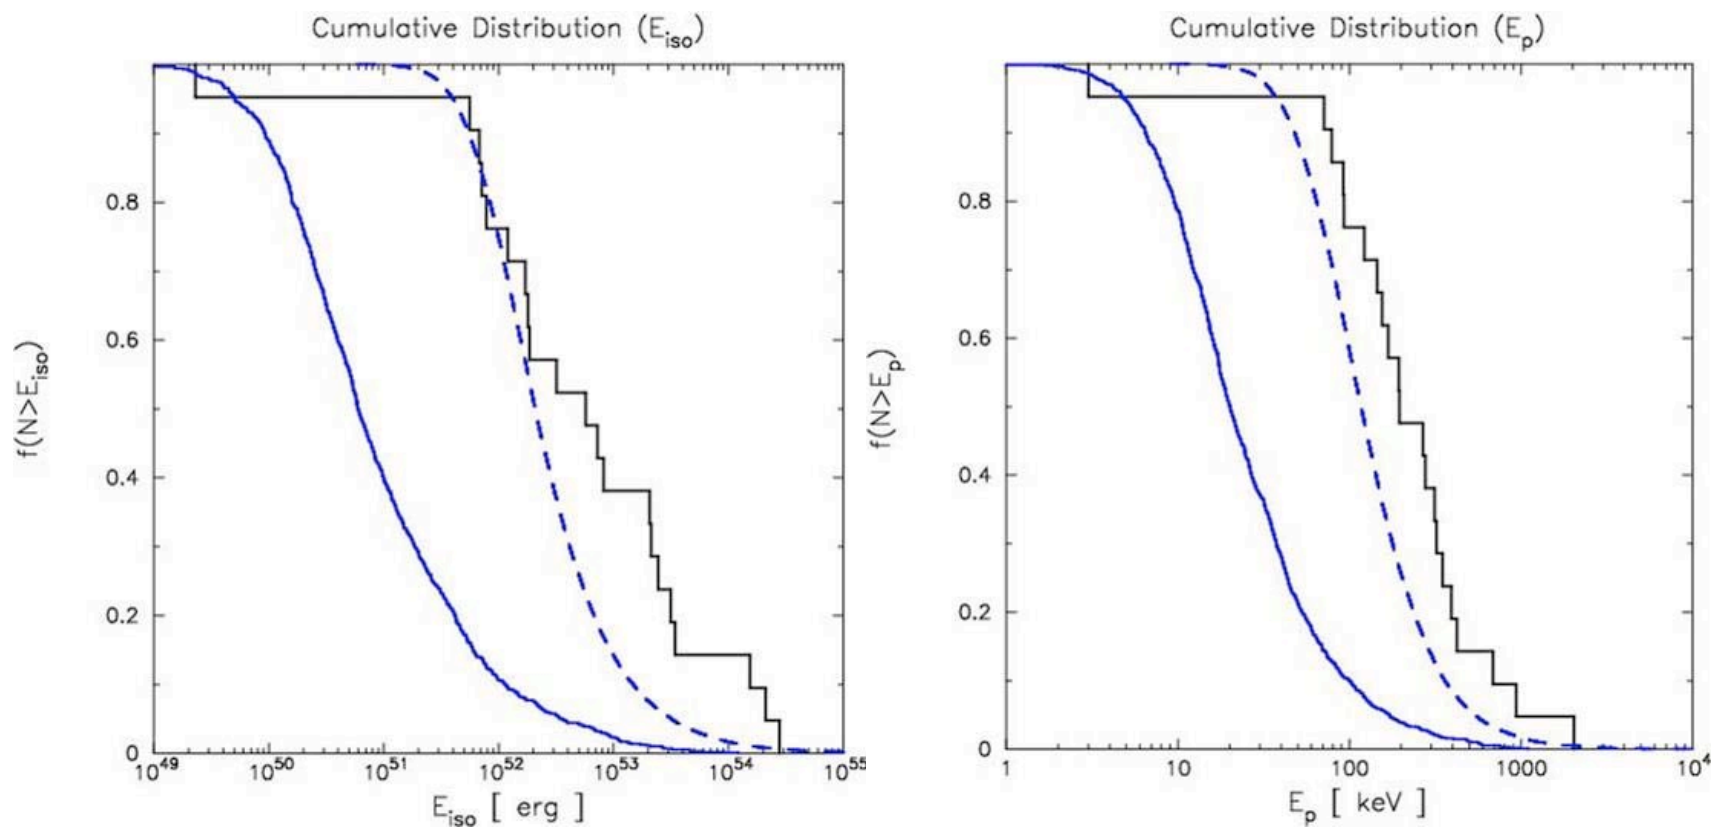

- ❑ Uniform jet model can account for *both* XRFs and GRBs
- ❑ Power-law universal jet model can account for GRBs, but not *both* XRFs and GRBs

# Comparison of Predicted and Observed $E_{\text{iso}}$ and $E_{\text{peak}}$ Distributions

Lamb , Donaghy, and Graziani (2003)

**Power-Law Universal Jet Model**

# Comparison of Predicted and Observed $E_{\text{iso}}$ and $E_{\text{peak}}$ Distributions

Lamb , Donaghy, and Graziani (2003)

**Uniform Jet Model**

# Gaussian Universal Jet Model

Zhang et al. (2004)

# Implications of the Uniform Jet Model

---

- ❑ Model provides unified picture of XRFs, “X-ray-rich GRBs,” and GRBs
- ❑ Extra parameter (distribution of jet opening solid angles  $\Omega_{\text{jet}}$ ) enables it to account for key result: *approximately equal numbers of bursts per logarithmic interval*
- ❑ Model implies that  $E_{\text{jet}}$  and  $E_{\text{gamma}}$  may be  $\sim 30$  times smaller than has been thought
- ❑ It will be important to determine whether bursts with much smaller values of  $E_{\text{iso}}$  and  $L_{\text{iso}}$  than the “standard” value are outliers, or are a sign that jet structure is more complicated
- ❑ This is particularly true in the case of XRFs, which may have considerably smaller values of  $E_{\text{iso}}$  and  $L_{\text{iso}}$

## Further Implications of Uniform Jet Model

---

- ❑ Model implies most bursts have small  $\Omega_{\text{jet}}$  (these bursts are the hardest and most luminous bursts); however, we see very few of these bursts
- ❑ Range in  $E_{\text{iso}}$  of five decades  $\Rightarrow$  *minimum* range for  $\Delta\Omega_{\text{jet}}$  is  $\sim 6 \times 10^{-4} < \Omega_{\text{jet}} < 6$
- ❑ Unified jet model therefore implies that there are  $\sim 10^5$  more bursts with small  $\Omega_{\text{jet}}$ 's for every such burst we see  $\Rightarrow$  if so,  $R_{\text{GRB}}$  may be comparable to  $R_{\text{SN}}$
- ❑ However, efficiency in conversion of  $E_{\text{gamma}}$  ( $E_{\text{jet}}$ ) to  $E_{\text{iso}}$  may be less for XRFs

# HETE-2 Bursts in $(S, E_{\text{peak}})$ -Plane
